The AP communicates with the STAs using beacon frames, which are periodically transmitted. The beacon frames typically carry information that a STA can use to find and associate with the AP. Associated STAs that transmit data to the AP transmit the data using data frames. Each frame transmitted to the AP may carry traffic for one or more of the STAs. Thus, the AP will typically transmit some frames to each associated STA in order to forward the data received from the associated STA to the data network. When a STA is associated with an AP, the STA may periodically transmit one or more association request frames, which are beacon frames that contain information indicating the STA's desire to associate with the AP. The AP responds to each association request frame with one or more association response frames that provide information to the STA about the current status of the AP. The AP also transmits a sequence of beacon frames that contain information indicating the STA's current association status. A STA that desires to associate with the AP may switch from using beacon frames to using data frames to transmit data to the AP. A STA that has already associated with an AP may periodically transmit one or more reassociation request frames, which are beacon frames that contain information indicating the STA's desire to switch its current association status to another AP. The AP responds to each reassociation request frame with one or more reassociation response frames that provide information to the STA about the current status of the AP. During the reassociation process, the STA may begin transmitting data to the new AP using data frames. The STA may periodically transmit one or more reassociation request frames, which are beacon frames that contain information indicating the STA's desire to switch its current association status to another AP. The AP responds to each reassociation request frame with one or more reassociation response frames that provide information to the STA about the current status of the new AP. Some wireless local area networks (WLANs) use enhanced IBSS (IBSS) on/off channels. One feature of enhanced IBSS on/off channels is the ability to implement a mesh network in which STAs with different roles, such as mesh STA and root STA, are connected in a mesh topology. The ST 82157476af
